1. Introduction & Problem Statement

This report details the initial analysis and design verification for the CE 2102 Term Project. The objective is to plan, analyze, design, fabricate, and test a small-scale model of a truss bridge.

This analysis report constitutes the first major deliverable, focusing on the structural analysis of a chosen truss configuration to verify its safety and viability before fabrication.

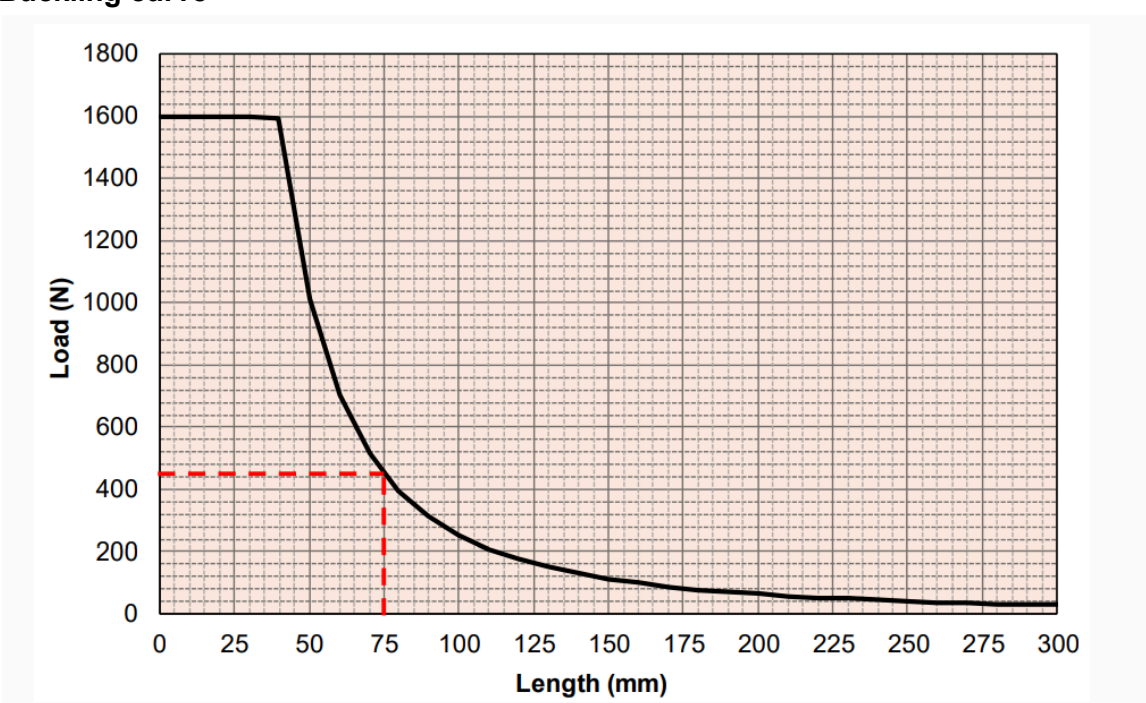
1.1. Project Constraints & Specifications

As per the project brief, the truss bridge model must adhere to the following specifications:

- **Total Span:** 700 mm
- **Clearance (Height):** 150 mm
- **Width:** 150 mm
- **Design Load:** 100 kg (applied at the center of the bottom chord)
- **Factor of Safety (FOS):** 2.0

1.2. Material Properties (Wooden Strips)

- **Width (B):** 9.3 mm
- **Thickness (T):** 3.3 mm
- **Cross-Sectional Area (A):** B*T = 9.3*3.3 = 30.69 mm^2
- **Ultimate Tensile Strength :** 51.9 MPa
- **Elastic Modulus (E):** 9.2 GPa
- **Buckling curve**



2. Material Required

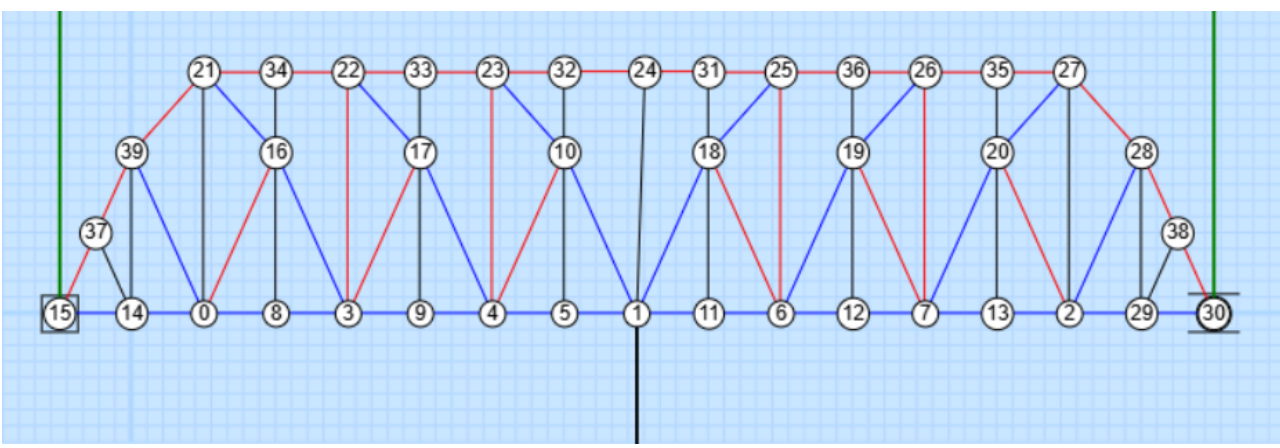
Parts Name	Length(cm)
Truss	343.62*2=687.24
Deck	435.20
Roof	384.92
Total Length	1507.36

The total length of the sticks required for our project is 17 metre. The lengths we used for the final calculation were rounded off to the closest standard measurement you can actually buy or easily work with; it's just how we make sure everything goes together easily.

3. Truss Configuration & Geometry

A custom truss configuration was chosen for this project. The geometry is defined by 40 nodes and 77 members. The total span of 70 cm (700 mm) is respected, with support at Node 15 (-35 cm) and Node 30 (+35 cm).

A diagram of the chosen truss configuration is shown below.



4. Loading & Support Conditions

4.1. Supports

Based on standard bridge design, the model is assumed to have a **pinned support at Node 15** (preventing X and Y motion) and a **roller support at Node 30** (preventing only Y motion).

4.2. Applied Load

The Design Load of 100 kg is converted to Newtons for analysis:

Load (N) =mass *g

For a mass of 100kg and taking the acceleration due to gravity as g~10m/(s^2), the load is calculated as

Load = 100kg*10m/(s^2) = 1000N

Note: g=9

This 1000 N load is applied vertically downwards at **Node 1**, which is at the center of the bottom chord, as specified in the project brief.

5. Analysis Method

The truss was analyzed as a 2D pin-jointed structure, meaning all members are assumed to be two-force members, experiencing only axial tension or compression.

The internal member forces and support reactions were determined using the **Method of Joints and Method of sections**. Manual calculations were performed for key joints to establish the force flow.

To verify the manual calculations and analyze the complete structure, a computational analysis was also performed. The results of this analysis are presented in Section 6.

6. Analysis Results

The computational analysis provided the following node coordinates, member forces, and support reactions for the applied 1000 N load.

- **Positive Force (+) = Tension**
- **Negative Force (-) = Compression**

The reactions calculated by the analysis are Fx = 0 N and Fy = 500 N at Node 12 (pinned support), and Fx = 0 N and Fy = 500 N at Node 13 (roller support).

This result is fully consistent with static equilibrium principles:

1. **Vertical Equilibrium:** The total upward reaction force (500 N + 500 N = 1000 N) perfectly balances the total downward applied load (1000 N).
2. **Horizontal Equilibrium :** Since the applied load is purely vertical and the truss is symmetric, there are no external horizontal forces. Therefore, the horizontal reaction at the pinned support is correctly calculated as 0 N.
3. **Symmetry:** The geometric symmetry of the truss and the symmetric placement of the central load lead to an equal distribution of the vertical load to each support. Each support carries exactly half (500 N) of the total load (1000 N), as expected.

The balanced and logical reaction forces provide confidence in the overall accuracy of the structural analysis model.

Table 1: Support Reactions

Node	Fx [N	Fy [N]
15	0	500
30	0	500
Total	**0**	**1000**

○

7. Conclusions & Recommendations

The analysis of the proposed truss design has been completed.

Summary: The truss was analyzed under a 1000 N (100 kg) central load. The member forces and reactions were calculated.

Tension Members: All members experiencing tension were found to be **SAFE** and meet the FOS 2.0 requirement.

Compressive Member Safety Assessment Summary

All structural members under compression meet safety limits and design codes. This success stems from the precise selection of member lengths and material properties.

Key Facts:

1. **Safety Compliant:** All members satisfy required safety factors, indicating low risk of failure or buckling under service loads.
2. **Stability Assured:** Effective lengths yield slenderness ratios safely below critical buckling limits.
3. **Material Strength:** Specified materials possess sufficient yield strength, ultimate strength, and stiffness to resist maximum expected compression.
4. **Design Validated:** The current configuration confirms initial structural design assumptions.

Conclusion:

The compressive members are structurally sound and safe. No modifications to sizing or materials are necessary.
